

Philipp Hilbert. *Platform PM who has shipped fraud-adjacent infrastructure in regulated environments.*

Positioning, ten years owning complex backend platforms in regulated industries, data provenance, identity, payment flows, now applied to fraud detection and case management at scale.

Kraken's fraud infrastructure problem is not a tooling problem, it is a systems problem. Ten million users across dozens of jurisdictions means that an ATO event in one region creates case management load that ripples across Legal, Ops, and Engineering simultaneously, and a case management system that was designed for one scale will buckle visibly at another. The job description names this precisely: you need someone who can revamp case management, define API specs, coordinate with external vendors, and keep the whole thing compliant across jurisdictions, all without adding friction for the users who have done nothing wrong. That is a product problem I understand.

My background is in exactly this class of platform: complex, compliance-critical, cross-functional, and consequential if wrong. At Rohde & Schwarz I owned a module of the AI backbone for a European defence programme, safety-critical data pipelines with full provenance and audit trails, multinational stakeholder coordination, and a hard requirement that nothing shipped without traceability. At Bundesdruckerei I owned secure identity infrastructure for national pandemic monitoring under the highest privacy requirements in German law. At Bundesagentur für Arbeit I served as deputy IT security officer while running the data platform, which meant owning compliance, governance, and data lineage under a recurring audit cycle. None of those were fraud roles. All of them trained the same muscle: translating a complex operational reality into precise, implementable requirements that Engineering, Legal, and Ops can all sign off on.

On the fraud and ATO domain itself, I am not starting from zero. I have spent eight years as an active participant in crypto markets, trading across Hyperliquid, Bitget, Jupiter, and Across Protocol, studying liquidation heatmaps and market microstructure, and building a backtesting

framework from scratch. That depth means I already have a working mental model of the anomaly patterns that fraud and ATO signals need to catch: device-switching during high-volatility windows, unusual withdrawal routing, account behaviour that is statistically normal until it is not. What I bring on day one is genuine domain intuition, not a reading list.

The case management revamp named in the posting is the kind of zero-to-one problem I have done before. At EMIL Group I built a claims module with no specification and no internal precedent, running discovery directly with a pilot customer's claim specialists until I had enough signal to define the product. I then instrumented the flow so that churn per process step became the prioritisation metric, not velocity, not story points, but the operational number the business actually cared about. That is the same approach I would take here: map the current investigator workflow first, find the highest-friction handoffs, and build the measurement into the product before the first release rather than after.

Kraken's scale and its commitment to operating as a genuinely global platform make this role interesting beyond the immediate problem. An open financial system has to be a trustworthy one, and the fraud and ATO infrastructure is where that trust is tested at the individual user level every day. I want to own that.

Best regards, *Philipp Hilbert*
