

Philipp Hilbert. *Requirements-to-delivery bridge for AI-powered B2B SaaS.*

Positioning, ten years of technical BA and product ownership across backend-heavy SaaS, ETL platforms, and API integrations, built for a role where the gap between business and engineering has real cost.

Nameless Ventures is building AI-powered iGaming software, a domain that combines real-time data pipelines, complex backend integrations, and a user base that holds the product to an unusually high standard. That combination is exactly what makes this role interesting to me, and it is the environment I have been building toward with the last decade of my career.

At Rohde & Schwarz I owned a module of the AI data backbone for the FCAS European defence programme. Practically, that meant translating multimodal sensor data requirements into reproducible, auditable ETL pipelines, writing the specifications that governed how data scientists and infrastructure engineers worked together, and owning the backlog through to production rollout. Deployment times dropped from several days to under 40 minutes after I resolved an infrastructure dependency that had been blocking engineering for over a year, not by writing the infrastructure myself, but by mapping the constraint clearly enough that the right people could solve it fast. That is the kind of translation work your posting describes.

At the Bundesagentur für Arbeit I introduced automated ETL orchestration across a national analytics warehouse, introduced CI/CD standards, and served as deputy IT security officer through recurring audit cycles. Governance, data lineage, and compliance under pressure are not abstractions to me. At EMIL Group I built a claims module from zero, no specification, no precedent, by running discovery directly with the pilot customer's claim specialists, then restructuring a 17-person delivery organisation that had stalled into teams that could genuinely own something end to end. Velocity returned. Client trust returned.

Beyond the professional record, I bring something specific to an iGaming context: years of serious poker play, including extended use of PokerTracker and Hold'em Manager and a period as a hand reviewer on PokerStrategy.com. That is not a footnote, it is direct product-user experience with the analytical tooling and feedback loops that serious players rely on, and it

informs how I think about what an AI-powered iGaming product actually needs to do to earn adoption rather than merely exist.

My working mode is AI-native. I use Claude Code, GPT, Cursor, and a multi-agent orchestration framework I built myself to compress the distance between a specification and a working prototype. That matters for a role at the intersection of backlog ownership and technical depth, because it means I can validate an idea at the interface level before it enters refinement, and I can review an API contract or a data schema directly rather than relaying questions through intermediaries.

The role is in Dubai. I am actively targeting the UAE and willing to relocate. This is not a location compromise, it is a deliberate direction.

Best regards, *Philipp Hilbert*
